Surprising research into dog sperm has reproductive biologists concerned about the fate of their own species. In a March study, scientists at Nottingham University found two chemicals common in home environments damage the quality of sperm in men and dogs.

The culprits implicated are diethylhexyl phthalate (DEHP), used to make new plastics more pliable, and polychlorinated biphenyl 153 (PCB153), found in older plastics and electrical equipment. Companies stopped producing PCBs in the late-1970s due to their health risks – including a possible increased risk of cancer, hormone disruption, liver damage and behavioural or cognitive deficits in children exposed in utero – but the chemical persists in the environment.

The Nottingham study is just one in a mounting pile of research indicating that the quality and quantity of men’s sperm is on the decline. Research suggests that sperm counts have dropped by half in the last 50 years or so and that a higher percentage are poor swimmers – slow, ungainly or beset by genetic flaws.

The exact cause of decline is not well understood. One culprit may be increasingly unhealthy lifestyles. The same factors that affect general health – being overweight or obese, smoking, stress and alcohol or recreational drug use – also affect the quality of sperm. But many researchers suspect chemical residues in the environment may be partly to blame.

To test that theory, the Nottingham researchers first removed contaminants from semen samples of men and dogs and then exposed them to manmade chemicals. Results showed exposure at levels found in the environment reduced sperm motility (ability to swim) and fragmented DNA carried in the head of the sperm.

The number of samples in the Scientific Reports study – nine from men and 11 from dogs – is too small to draw conclusions about cause and effect, says lead author Richard G Lea, an associate professor of reproductive biology at the University of Nottingham’s School of Veterinary Medicine and Science. “Of course we have to be cautious based on these numbers,” he says. “But our data add to the weight of evidence that chemicals in the home environment degrade sperm.”
If the cause is environmental, you would expect to see a similar effect on man’s best friend, says Lea. “Dogs live in our homes. They often even accompany us to work,” he says. “They share our environment basically so they’re exposed the same chemical contaminants.” And, indeed, in a 2016 study of sperm collected from stud dogs, Lea’s team discovered that the number of good swimmers decreased by 30% over a 26-year period. Declining sperm counts are an “indicator that there is something very wrong in our modern environment or lifestyle”, says Dr Hagai Levine, head of the environmental health track at the Hebrew University–Hadassah Braun School of Public Health in Israel. “We need to identify what the causes are and fix them. Otherwise it’s dangerous to our future and maybe irreversible.”

Part of the problem is certainly the way we work and live. Being stressed and sedentary is no good for sperm and it’s worse if you smoke, drink alcohol or use recreational drugs. For example, a large review of studies from 26 regions across the world found that smoking decreased sperm by 13–17%. Another study found smoking marijuana regularly (more than once weekly) lowers sperm count in young men and the effect is exacerbated when they also use other recreational drugs.

There’s also a growing consensus that some chemicals found in everyday products such as plastic bottles, metal food cans, detergents, flame retardants, food, toys, cosmetics and pesticides can affect a man’s reproductive health. Those chemicals, referred to as “endocrine disruptors” interfere with the body’s natural hormone systems – by blocking production or effects of the male hormone testosterone, for instance.

Those effects may begin while babies are still developing in the womb says Niels Skakkebæk, professor at the University of Copenhagen and senior researcher at the department of growth and reproduction at Rigshospitalet in Denmark. He points out that poor sperm quality is associated with an increased risk of testicular cancer and also a history of congenital reproductive defects, including undescended testes. One theory is that all those conditions are linked to the mother’s exposure to environmental contaminants at critical moments during pregnancy when the baby’s sex organs develop.

Endocrine disruptors may also affect sperm in adult men. A 2014 study of the effects of 96 chemicals on human sperm found that they affected sperm’s ability to swim, navigate and fertilise an egg. Chemicals from plastics are particularly worrisome because they are so ubiquitous. Roughly two-thirds of the plastic ever produced has been released into the environment and shows up as tiny particles in the air, water and soil. Eventually those plastics collect in the tissues and fluids in our bodies. Lea says he focused on two compounds that “consistently popped up” in his analysis of dog food, sperm and testes tissues from routine neutering procedures. But there are many others he’d like to study. “The reality is I’ve only looked at two chemicals, but we live in a cocktail of pollutants,” he says.

Last year, Levine and other scientists, public health officials and clinicians from around the world issued a statement calling on governments, the scientific and medical communities, and organisations to acknowledge the importance of male reproductive health, to allocate resources to study the issues and to implement policies that remove hazards and
promote a safer environment. The plea did not draw as much attention to the problem as he had hoped.
The most obvious concern of falling sperm counts is infertility. Even with sperm counts in decline, most men retain their fertility potential, says Skakkebæk. But birthrates have been declining in industrialised countries for decades, he says, and it’s not clear that this is entirely by choice.
Recent studies suggest 20-30% of young men today have sperm counts in a range that is associated with reduced fertility, says Skakkebæk.
Some research suggests we may be reaching “a tipping point” where more couples will take longer to conceive or may need the help of assisted reproductive technology such as in vitro fertilisation (IVF), he says. He points out that in Denmark, the number of couples seeking help for infertility has increased significantly since 2001. “Almost 10% of children are now born after assisted reproduction,” he says
Current estimates are that 12–18% of couples have problems conceiving, but there isn’t good data to show how that is changing over time. Most researchers view the declining population data in western countries as a worrisome trend, but there is nothing to link that specifically to sperm decline.
There’s also a concern that decreasing quantity and quality of sperm is a marker for worsening health in general, Levine adds. Research has linked problems with sperm to a higher risk of a number of serious health conditions, including cancer, diabetes and heart disease, as well as death. “I do see an analogy to climate change in the sense that we have clear scientific signs of the problem – a very serious problem, which endangers humanity,” he says. “But we are not taking the needed steps to reverse it or even just to start to understand what is going on.”
